This study was undertaken to define the mechanism of DNA damage induced in human leukocytes by drug treatment and by nitric oxide (NO). Malarial parasite-derived drug, WR99210, induced DNA single-strand breaks and also DNA-protein cross-links. DNA single-strand breaks were also induced by the antifolate, WR-2721. Treatment of human leukocytes with NO donors, sodium nitroprusside or S-nitrosoglutathione, induced the appearance of DNA single-strand breaks. A time-course study of the DNA single-strand breaks by NO donors revealed that the NO could be removed by iron chelators, deferoxamine (DFO) or desferoxamine (DFO). Examination of the effect of these iron chelators on NO-induced DNA single-strand breaks revealed that they did not inhibit NO-mediated DNA single-strand breaks. Electrophoretic studies showed that NO alone could produce DNA cross-links which were repaired by cell-free DNA-ligase assay. However, NO-treated cells were unable to repair these cross-links. DFO or DFO plus deferasirox (DF) treatment did not enhance the DNA damage in NO-treated cells. Hence, iron chelators were not effective in repairing DNA damage induced by NO. Our results indicate that DNA damage was induced by NO and iron chelators are not effective to repair the DNA damage induced by NO.
