One of the latest scientific studies on the effects of chronic exposure to chemicals indicates that there is a link between the residential proximity to arsenic-contaminated waterways and the increased occurrence of cancer. "This study calls for additional research to help us understand the mechanisms behind arsenic-related cancers and determine whether the risks posed by arsenic exposure are cumulative," said Dr. Margot Kushel, of Penn State University. "Most people in the U.S. have been exposed to arsenic in their drinking water for generations and we hope that this and future studies will help to identify safe levels of exposure and to encourage the public to make responsible use of the water supply." Arsenic is a chemical element that can cause cancer. It is naturally occurring in rocks and soil, and in recent years, water contamination has created a widespread problem. The main sources of arsenic in drinking water are arsenic-laced ground water and old pipes, according to the U.S. Environmental Protection Agency (EPA). According to the EPA, more than 12 million Americans have unsafe levels of arsenic in their drinking water. While only about 10 percent of people exposed to high levels of arsenic have been diagnosed with cancer, it is clear that an association exists. Besides the proven link between arsenic and cancer, those exposed to arsenic have an increased risk of cardiovascular disease, hypertension, lung disease and reproductive disorders. The arsenic-related cancerous and pre-cancerous effects are primarily seen in the kidney, urinary bladder and skin, and are most likely due to heavy exposure to arsenic over a long period of time. Arsenic can enter the body through food, air and through water. If the body is exposed to high concentrations of arsenic, it can accumulate in the body. Exposure to arsenic has been linked to an increased risk of cancer in a wide range of other countries, including those in Chile, China and Bangladesh. "Carcinogens are chemicals that cause cancer, and they often are present in the environment at trace levels. From these studies, it is clear that arsenic is a carcinogen and that exposure to arsenic is a problem that must be solved," said Dr. Kushel, who is also the principal investigator of the National Institute of Environmental Health Sciences' National Childhood Cancer Program. "We must also stop the exposure of people
