Use Windows Explorer's file size distribution function to visualize your hard drive's disk space utilization and get a breakdown of volume use by different file types, including subfolders. Advertisement Like this: As September is almost over, it's time to decide if you want to install or uninstall certain programs. The only exception to the rule in this matter are programs that have a re-install option available, as some of the applications you delete may be re-installed if you use the uninstaller function. In this article, we'll focus on clearing the cache space in Windows 10. First things first, let's see what that means. What's the difference between the cache and the temp directory? Well, technically speaking, the cache is temporary storage for files that are currently being used in Windows to speed up a program's performance, while the temp directory

---

contains files that are created by the programs for specific use. In short, you can clearly see that temporary files such as program files, user files, and others are created by the programs and moved to the temp directory, and then to the cache. Why should you clear the cache? Well, the cache is where frequently accessed files are stored, the more often a certain file is used, the more likely it is that it's stored in the cache.

As a rule of thumb, you should definitely clear the cache on a regular basis. In addition, if you have a slow computer, the cache is one of the most often used components, and when your cache is full of files, it can end up affecting your Windows performance in extreme cases. Basically, this means that programs may function slower, since they're forced to access the storage media, even if it's not actually loaded in memory. If you clear the cache, you can easily relaunch some programs or apps, since the data is reloaded into the cache, and even though it's not cached at the moment, the data will be reloaded when that application is loaded.

Another reason to clear the cache is that the Windows Task Manager shows that the Windows cache is constantly being used to refresh the data, even though it's not actually being used. As you can imagine, this leads to a full or even over-full cache, and as Windows cannot identify which programs to delete from the cache, Windows software manager shows you a bunch of applications to clear the cache for. b7e8fdf5c8
